

VERSION WITH MARKINGS TO SHOW CHANGES MADE

METHOD FOR FABRICATING AN OLFACTORY RECEPTOR-BASED  
BIOSENSOR

5

This application is a continuation-in-part of application 09/057,181 filed April 8, 1998, the entire disclosure of which is incorporated herein by reference.

FIELD OF THE INVENTION

10

The present invention related generally to biosensors and, more specifically, to biosensors which have biomolecules attached to a thin film transducer.

BACKGROUND OF THE INVENTION

15

Chemoreception is an ancient sense system that enables organisms to detect chemicals in its environment. In humans, odor receptor cells are located in the nose. The biochemical receptors for the odorants are transmembrane proteins found in the membrane of receptor cells cilia. Olfactory receptor proteins (ORP) generally have  
20 seven non-intersecting helices. It is believed that conserved residues determine the orientation of each helix relative to the other helices.—

The detection of environmental chemicals is mediated by peripheral olfactory organs of varied complexity in almost all metazoans. Typically, specialized sensory neurons initiate perception by detecting ambient molecules, commonly called odors,

that interact with protein receptors in their membranes. ORP on the cilia detect the odorants entering the nose. The ORP are coded by approximately 1000 genes, and it is the largest gene family in the genome of any species. ORP are members of the proteins having seven transmembrane domains, i.e. G-protein couple receptor (GPCR) superfamily. They have a diverse amino acid sequence and are able to recognize a wide variety of structurally diverse odorants. The amino acid sequences of ORP are especially variable in the several transmembrane domains. This is a possible mechanism for the recognition of a variety of structurally diverse ligands.

The major path of olfactory transduction is shown in Fig. 1. Binding of the odor molecules to the receptors may activate a G-protein coupled enzymatic cascade to generate second messengers. These messengers can open the ion channels on the membrane of olfactory cells. The opening channels may depolarize the membrane and lead to action potentials and signaling.

~~When the odor molecule binds to the receptor (in the transmembrane regions), it is believed that the receptor molecules changes shape. This apparently activates a G-protein on the intracellular surface of the cilia which in turn binds to a G-protein receptor on the ORP. (Olfactory G-protein receptors are one of the largest groups of G-protein coupled receptors described to date.) Olfactory G-protein linked receptors then trigger the biochemical synthesis of neurotransmitters which open eation channels that ultimately lead to action potentials and signaling, i.e. the sense of smell. In other words, the chemical stimulus is transduced into a neural event. The major path of olfactory transduction is shown in Figure 1 of the drawings.~~

There is currently a need for sensors which function like an ORP ~~can being~~

~~capable of detecting ligands, i.e. certain gas molecules, to be developed. of the type~~  
~~which bind to olfactory receptor proteins. The goal, then, is to assign functional~~  
~~odorants to specific olfactory receptors and to develop useful sensors for detecting~~  
~~the presence of the odorant~~certain gas molecules according to the assignment of the

5 certain gas molecules binding to certain sites of an ORP. It has been difficult in the  
past, however, to rapidly determine the secondary and tertiary molecular structures of  
ORP's having olfactory receptor binding domains specific to selected ligands of  
interest. This is due in part to the complexity of ORP molecules. ~~As will be~~  
understood by those skilled in the art, in an empirical analysis, a determination of  
10 putative binding domains is an extremely labor-intensive endeavor. It begins with  
identification and molecular cloning of genes that code for the receptor protein of  
interest. These genes are then expressed and the target protein is isolated and  
purified. Physical studies such as X-ray diffraction, neutron diffraction and electron  
microscopy are conducted to determine 2-D maps and 3-D structure; site directed  
15 mutagenesis is conducted to determine the position of residues for ligand binding. It  
would be desirable to provide a method which eliminates as many of these steps as  
possible.

~~Thus, it is an object of the present invention to provide a method for rapidly~~  
~~determining ORP candidates for use as receptors for preselected odorant molecules.~~

20 ~~It is a further object of the present invention to provide a method for fabricating a~~  
~~biosensor which includes a layer of polypeptides that selectively binds a preselected~~  
~~odorant molecule.~~

## SUMMARY OF THE INVENTION

In one aspect, the present invention provides a method for rapidly determining ORP candidates for use as receptors for preselected odorant molecules.

5        In another aspect, the present invention provides a method for fabricating a biosensor which includes a layer of peptides that selectively binds a preselected odorant molecule.

~~Accordingly~~~~In one aspect,~~ the present invention provides a method for making a biosensor capable of detecting a gas molecule, wherein the gas molecule is a  
10    ligand ~~for~~ capable of binding to an olfactory receptor protein. The method includes the steps of determining the amino acid sequence of a preselected olfactory receptor protein the secondary and tertiary structures of which are not known. Typically this step will be carried out by choosing an ORP from a database of ORP's which have been sequenced. In the next step the ammo acid sequence of the ORP selected in  
15    the first step is compared to the sequence of G-coupled protein receptors having known secondary and tertiary structures. This step will typically be carried out by accessing a database of G-protein receptors having known primary, secondary and tertiary structures. Next, based on primary sequence homology, one or more G-coupled protein receptors is~~are~~ chosen as a candidate on which to predict the  
20    secondary and tertiary structure of the unknown ORP. In the next step, the secondary and tertiary structures of the unknown ORP are approximated based on the known structures of the G-protein receptor selected through sequence homology comparison in the prior steps. The approximated secondary and tertiary structures of the unknown ORP are then analyzed using conventional modeling techniques to

identify likely binding domains for the ligand of interest. A polypeptide is then synthesized having the primary sequence of the most likely binding domain for the ligand. These polypeptides are attached to a transducer. The resultant biosensor is then tested by exposing it to the target ligand and determining binding efficiencies.

5 By identifying and testing a number of polypeptides in this manner, high affinity biosensors can be rapidly fabricated.

~~Figure 5 is a table illustrating frequency changes resulting from attachment of ligands to a polypeptide made in accordance with the present invention.~~

## DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

The detailed embodiment of the present invention is disclosed herein. It should be understood, however, that the disclosed embodiment is merely exemplary of the invention, which may be embodied in various forms. Therefore, the details disclosed herein are not to be interpreted as limited, but merely as the basis for the claims and as a basis for teaching one skilled in the art how to make and/or use the invention.

Fig. 2 is a flow chart illustrating the modeling steps of the preferred embodiment. Referring now to ~~Figure~~ Fig. 2 of the drawings, an olfactory receptor protein which has been sequenced is selected in step 210. Of course, it may be desirable in some cases to actually clone, express, isolate and sequence a new ORP; however, in most instances an ORP will be chosen from a sequence database having the primary amino acid sequence of various ORPs. One preferred database for use in the present invention is available on the ExPASy server of the Swiss Institute of Bioinformatics. Other similar databases or print sources may be equally suitable.

Once the ExPASy server has been accessed, ~~the file entitled~~ the "SWISS PROT and TrEMBL—~~protein sequences~~" database is opened. The ExPASy server is open to the public and may be accessed via the Internet. Next, using the keyword search features of this file, the key words "olfactory receptor" may be used to create a subset of sequences of olfactory receptor proteins. An ORP is then selected, the sequence of which is to be used in the practice of the invention. The known sequence is displayed along with additional information on the ORP such as EMBL cross references, length and molecular weight. The amino acid sequence

information is generally subdivided into potential extracellular, transmembrane and cytoplasmic domains, which are predicted and provided only for reference. For example, an ORP, OLFD CANFA (P30955), is selected from the "SWISS PROT and TrEMBL" database. The amino acid sequence is shown on Fig. 3, and the predicted secondary-structure features of OLFD CANFA (P30955) are listed in Table 1.

Table 1

In the next step of the invention, the sequence of the ORP of unknown secondary and tertiary structures is compared to sequences of proteins having known sequences and known secondary structures. Most preferably, the database

of proteins with known secondary structures is comprised of G-coupled receptor proteins. It will be appreciated by those skilled in the art that olfactory receptor proteins are a class of G-coupled receptor proteins. This comparison is preferably carried out using a publicly available database. Most preferably, In step 220 of Fig.

5 2, the predicted secondary structure, such as  $\alpha$ -helix,  $\beta$ -sheet, and transmembrane regions, of the ORP under investigation is determined by using, for example, the "PredictProtein" server of the "BIOcomputing 3D Modeling Unit Service" webpage (B Rost: PHD: predicting one-dimensional protein structure by profile based neural networks. Methods in Enzymology, 266, 525-539, 1996 PredictProtein: B Rost  
10 (1996) Methods in Enzymology, 266:525-539; Url: <http://dodo.cprmc.columbia.edu>). The "PredictProtein" server can be accessed through worldwide web sites. The service of "PredictProtein" includes sequence analysis and structure prediction. One can submit any protein sequence, and then "PredictProtein" retrieves similar sequences in the database and predicts aspects of protein structure. The  
15 "PredictProtein" server uses includes the following several programs and database, such as those listed in Table 2, to predict protein's structure.

Table 2

<u>Program's Type</u>	<u>Program</u>	<u>Function</u>
<u>Alignment and database searching methods</u>	<u>MaxHom</u>	<u>MaxHom is a dynamic multiple sequence alignment program which finds similar sequence in a database.</u>
	<u>ProSite</u>	<u>ProSite is a database of functional motifs.</u>

<u>Sequence motif searching methods</u>	<u>ProSite</u>	<u>ProSite is a database of functional motifs.</u>
<u>Sequence motif searching methods</u>	<u>ProDom</u>	<u>ProDom is a database of putative protein domains; searched with BLAST for domains corresponding to sequence being investigated.</u>
	<u>PMDacc</u>	<u>PMDacc predicts per residue solvent accessibility from multiple sequence alignments.</u>
	<u>PHDhtm</u>	<u>PHDhtm predicts the location and topology of transmembrane helices from multiple sequence alignments.</u>
	<u>GLOBE</u>	<u>GLOBE predicts the globularity of a protein.</u>
	<u>TOPITS</u>	<u>TOPITS is a prediction-based threading program, that finds remote structural homologues in the DSSP database.</u>
	<u>COILS</u>	<u>COILS finds coiled-coil regions in your protein.</u>
	<u>EvalSec</u>	<u>EvalSec evaluates secondary structure prediction accuracy.</u>

~~∴ PHDsec (predicts secondary structure from multiple sequence alignments),~~

~~PMDacc (predicts per residue solvent accessibility from multiple sequence alignments), PHDhtm (predicts the location and topology of transmembrane helices from multiple sequence alignments), GLOBE, TOPITS, MaxHom (dynamic multiple sequence alignment program which finds similar sequence in a database), EvalSec, COILS, ProSite (finds functional motif in the sequence being investigated), SEC and ProDom (database of putative protein domains; searched with BLAST for domains corresponding to sequence being investigated) programs.—~~

In essence, these servers allow the sequence of the ORP to be submitted for comparison to the sequences of proteins in the PredictProtein database. PredictProtein retrieves similar sequences and predicts secondary protein structure

based on data for similar sequences. PredictProtein performs and displays the results of a "PROSITE" motif search, "ProDom" domain search, MAXHOM alignment header analysis, and provides information regarding accuracy of the forgoing analyses. This prediction of secondary structure is performed by PredictProtein  
5 using a system of neural networks.—

The MAXHOM program produces a multiple sequence alignment file which serves as the input for the neural network system. The output of the MAXHOM analysis includes identification of aligned proteins, percentage of pairwise sequence identity, percentage of weighted similarity, number of residues aligned, number of  
10 insertions and deletion (indels), number of residues in all indels, length of aligned sequences and a short description of the aligned proteins. The preferred neural network for prediction of secondary structure is described in "Prediction of Protein Structure at Better than 70% accuracy" J. Mol. Bioi., 1993, 232, 584-599, and the entire disclosure of which is incorporated by reference.

15 Prediction of solvent accessibility is also determined (PHDacc) in accordance with "The Analysis and Prediction of Solvent Accessibility in Protein Families" Proteins, 1994, 20, 216-226, and the entire disclosure of which is incorporated by reference. The latter prediction provides values for the relative solvent accessibility. Prediction of helical transmembrane segments of the ORP is performed by the  
20 PHDhtm program. In this manner, the secondary structure (helix, sheet, loop) and location relative to the membrane (inside, outside, transmembrane) for the ORP under investigation is predicted with relative accuracy. Most preferably, the predicted topology for the transmembrane proteins is determined using PHDtopology and fold recognition is determined by predicted-based threading using PHDthreader.

Again, the secondary structure predictive determinations are verified for accuracy using EvalSec. All of the computer programs used in the present invention can be accessed by the public, and their disclosures are incorporated herein by reference. (see, [embl-heidelberg.de/tmap\\_info.html](http://embl-heidelberg.de/tmap_info.html)).

5        For example, primary amino acid sequence of OLFD CANFA (P30955) is input into the "PredictProtein" server. Since most of odorant molecules bind to transmembrane helices of an ORP, the predicted seven transmembrane helices of the OLFD CANFA (P30955) are listed in Table 3.

10        Table 3

15        In Fig. 2, a~~Based on the results of the secondary structure prediction analysis,~~  
~~the sequences for~~for determining the predicted seven transmembrane helices ~~are~~  
~~determined.~~ Next, a template protein used to predict the approximated tertiary  
structure of the transmembrane helices are ~~determined~~selected in step 230. Most

~~preferably~~ This is preferably achieved in the ~~present invention~~ preferred embodiment using the Swiss-Model ~~7TM~~-interface program and, preferably, BLAST (Basic local alignment search tool as described in J. Mol. Biol. 215:403-410, the entire disclosure of which is incorporated herein by reference). To begin, the complete sequence of the ORP under investigation is input ~~in the BLAST program through Swiss-Model interface, which and then~~ then the BLAST program determines the most appropriate modeling template to be used in the tertiary structure investigation. The modeling template will be that protein (of known primary, secondary and tertiary structures) having the highest primary sequence homology and similar secondary structure with the ORP to be investigated.

For example, the primary amino acid sequence of the ORP, OLFD CANFA (P30955), is input through the Swiss-Model interface. ~~In other words, using BLAST,~~ The primary sequence of the OLFD CANFA (P30955) ORP under investigation is compared to the sequences of proteins in the 7TM (seven transmembrane) subset of the SWISS-PROT database by the BLAST program, since OLFD CANFA (P30955) also has seven transmembrane helices. Then, a number of BLAST-assisted templates, as listed in Table 4, are obtained. In Table4, Neuropeptide Y1 receptor (P25929) has the largest P(N). That is, Neuropeptide Y1 receptor (P25929) has the highest primary sequence homology with the OLFD CANFA (P30955). Hence, Neuropeptide Y1 receptor (P25929) is selected to be the modeling template of OLFD CANFA (P30955).

\*NA: not available.

After the modeling template has been selected, the sequences of the helical regions are displayed and the sequences of the helices of the ORP under investigation (as determined in the secondary structure analysis step of the present invention) are input (through Swiss-Model 7TM-interface program in step 240). That is, the helical regions of the template are aligned with the helical regions of the ORP under investigation. The comparison yields a prediction of the tertiary structure (3D in space) of the ORP being investigated on an atom-by-atom basis.

The tertiary structure of the ORP being under investigated is preferably output as a file containing three coordinates of each atom in the ORP. For example, a lengthy

list of three coordinates of each atom in the OLFD CANFA (P30955) was obtained.

The preferred protocol ~~for this step takes taken~~ into consideration for the step  
240 includes energy minimization and the like as described in: PromMod and  
Swiss-Model: Internet-based Tools for Automated Comparative Protein Modeling,  
5 Biochem. Soc. Trans. V. 24 274 1996; Large-Scale Comparative Protein Modeling,  
Proteome Research: New Frontiers in Functional Genomics 177 1997; Swiss-Model  
and the Swiss-PDBviewer; an Environment for Comparative Protein Modeling,  
Electrophoresis, V. 18 2714 1997; Automated Modeling of the Transmembrane  
Region of G-Protein Coupled Receptor by Swiss-Model, Receptors; and Channels v.  
10 4 161 1996; Protein Modeling by email, Bio/Technology V. 13 658 1995, the  
disclosures of which are incorporated by reference.

(The preferred modeling software programs which can be used in the present  
invention have a high degree of sophistication. For example, ProMod, which is  
under SWISS-MODEL Repository of the ExPASy Molecular Biology Server, applies a  
15 Protein Modelling tool which requires similarities with experimentally determined  
protein structures. ~~ProMod~~ It is a knowledge-based approach to predictive structure  
determination. It requires at least one known 3D structure of a related protein and  
good quality sequence alignments; the degree of sequence identity affects the  
accuracy of the predictive structure. In ProMod, there is a superposition of related  
20 3D structures. A multiple alignment with the sequence under investigation is made.  
A framework for the new sequence is made and any missing loops are rebuilt. The  
backbone of the structure is completed and corrected if required. Side chains are  
corrected and rebuilt. The resultant structure is verified and packing is checked.  
The structure is then refined by energy minimization and molecular dynamics

considerations.)

The tertiary structures of the helices of the ORP under investigation are thus determined in step 240 and may be viewed stereoscopically using a program such as Insight II, a commercial program provided by Molecule Simulations Inc. Accelrys Inc. ~~and now is provided by Accelrys Inc., or~~ Swiss PDB-viewer or the like. Next, in step 250, a ligand, i.e. a gas, ~~preferably one which is known to bind to the ORP under investigation,~~ is selected. A number of assays may be used to determine high general binding affinities of various ligands for the ORP under investigation. The molecular structure of the ligand and the ORP under investigation is then input to the Insight II program, i.e. the tertiary or 3D structures of ORP helices and the ligand are input. Next in step 260, the most probably geometrical binding domains of the ORP under investigation and the ligand are determined, preferably using the Global Range Molecular Modeling program (GRAMM) ~~which utilizes~~ by geometric recognition algorithms. As ~~will be~~ understood by those skilled in the art, GRAMM is a program for protein docking, and it treats the ORP and the ligand as rigid bodies. Since GRAMM utilizes geometric recognition algorithms to determine the most probably geometrical binding domains of a protein for a ligand, no specific information about the binding sites is required. It performs a six-dimensional search through the relative translations and rotations of molecules. It takes an empirical approach to smoothing the intermolecular energy function by changing the range of atom-atom potentials. It allows the user to locate the area of the global minimum of intermolecular energy for structures of different accuracy.

Then in step 270, the structures of the ORP and the ligand are allowed to relax.  
That is, the structures of the ORP and the ligand are flexible. Hence, the bond

stretching, valence angle bending, torsion, van der Waals force, and electrostatic force of both the ORP and the ligand are taken into consideration. Affinity Docking program, an embedded program of Insight II, may then be preferably used to calculate the energy distribution and reaction forces between the ligand and the geometrically predicted binding domains, as predicted by GRAMM, of the ORP by molecular mechanics calculations using the energy minimization algorithm. The most probably overall binding domains are thus determined, and the user can read out the sequence of the binding domains by move the mouse to each amino acid of the binding domains.

For example, the most probably binding domains, as shown in Fig. 4, of the OLFD CANFA (P30955) for trimethylamine is predicted. The trimethylamine molecules are shown as spherical molecular model, and the OLFD CANFA (P30955) is shown as cartoon structure. The eight most probably binding domains of the OLFD CANFA (P30955) for the trimethylamine are located in transmembrane 1, transmembrane 3, and transmembrane 5.

~~Polypeptides~~ Peptides are then synthesized corresponding to these most probably binding domains using conventional synthesis technologies. The polypeptides are then applied to the surface of a transducer, preferably one fabricated using thin film (semiconductor) technique as will be known to those skilled in the art. Briefly, with reference to ~~Figure~~ Fig. 35, ~~biosensor 10 is seen having~~ transducers ~~42-510~~ coated with polypeptide layer 44520 are on biosensor 500. Transducer ~~42-510~~ is preferably a piezoelectric quartz crystal-based device. A new change will occur if a ligand binds to the polypeptide layer resulting any a-measurable frequency change in the quartz crystal frequency, allowing detection of ligand binding.

The success and efficiency of the transducer can be determined, including by comparing the sensor's response to the ligand and other molecules.

For example, peptides synthesized according to the most probably binding domains of OLFD CANFA (P30955) for trimethylamine are peptides B1, B2, and B3.

5 The amino acid sequences of the peptides B1, B2, and B3 are DPDQRDC, GDLESFC, and CFFLFFGD. These peptides all have or are added a cystein (symbol C) residue at one terminal. The transducers of a biosensor have gold electrodes, the –SH functional group of the cystein can react with gold electrodes directly in an organic solution to form chemical bond between them. Hence, a

10 simple way to attach these peptides is dipping the surface of gold electrode on piezoelectric quartz with the peptide solution under room temperature for a period of time. Therefore, these peptides can be attached on the surfaces of the transducers. Then, after attaching these peptides on the transducers of a biosensor, the biosensor is used to detect various gases such as trimethylamine, dimethylamine, ammonia,

15 acetone, formic acid, ethanol, and formaldehyde. The experimental results of the peptides B1, B2, B3, and Pb2 are listed in Table 6, wherein the peptide Pb2 is not designed according to the most probably binding domains of the ORP, OLFD CANFA (P30955).

20 Table 6

<u>Gas detected</u>	<u>Frequency changes (Hz)</u>			
	<u>B1</u>	<u>B2</u>	<u>B3</u>	<u>Pb2</u>
<u>Trimethylamine (5.86 ppm)</u>	<u>5696</u>	<u>488</u>	<u>687</u>	<u>221</u>
<u>Dimethylamine(3.78 ppm)</u>	<u>3851</u>	<u>578</u>	<u>721</u>	<u>589</u>

<u>Ammonia (4.86 ppm)</u>	<u>1022</u>	<u>206</u>	<u>209</u>	<u>345</u>
<u>Acetone (7.21 ppm)</u>	<u>13</u>	<u>9</u>	<u>9</u>	<u>31</u>
<u>Formic acid (1.33 ppm)</u>	<u>161</u>	<u>56</u>	<u>85</u>	<u>97</u>
<u>Ethanol (4.68 ppm)</u>	<u>-5</u>	<u>6</u>	<u>-5</u>	<u>16</u>
<u>Formaldehyde (6.54 ppm)</u>	<u>-25</u>	<u>-22</u>	<u>-27</u>	<u>19</u>

Peptide sequence of B1: DPDQRDC

Peptide sequence of B2: GDLESFC

Peptide sequence of B3: CFFLFFGD

5 Peptide sequence of Pb2: LFLSNLSFSDLCA

In Table 6, the numbers shown on each column under each peptide are frequency changes of the quartz crystal vibration frequency. Hence, the absolute value of the number is larger, and the sensitivity for the gas detected is larger. For  
10 the desirable detected gas, trimethylamine, all peptides B1, B2, and B3 show a much more sensitive response then the peptide Pb2 designed by other methods.

It will be apparent to those skilled in the art that various modifications and variations can be made to the structure of the present invention without departing from the scope or spirit of the invention. In view of the foregoing, it is intended that  
15 the present invention cover modifications and variations of this invention provided they fall within the scope of the following claims and their equivalents.

Examples:

~~The following examples are intended to further illustrate the present invention.~~

~~A G-Protein Coupled Receptor database was accessed and the sequence of~~  
20 ~~an ORP of known primary sequence, but unknown secondary and tertiary structures~~

was retrieved (SWISS-PROT: P30955) as shown in Figure 4. It consists of 330 amino and has a molecular weight of 35197 daltons. The secondary structure was predicted and its accuracy verified through the use of MaxHom, PHDsec, PHDacc, PHDhtm, PHDtopology, PHDthreeder and EvalSec. The transmembrane sequence regions were thus obtained. A BLAST assisted template was then selected: Neuropeptide Y1 receptor (Homo sapiens). Trimethylamine was selected as the ligand. Using GRAMM, several possible binding domains were identified and corresponding polypeptides were generated. In Figure 5, (poly)peptide B1 designed in accordance with the present invention illustrates better response for trimethylamine than another (poly)peptide Pb2.

## CLAIMS

What is claimed is:

5           1. A method of making a biosensor capable of detecting a molecule, wherein the molecules is a ligand ~~for~~ being capable of binding an olfactory receptor protein, said method comprising the steps of:

10           (a) ~~D~~determining the amino acid sequence of a preselected olfactory receptor protein, the secondary and tertiary structures of said olfactory receptor protein being unknown;

15           (b) ~~C~~comparing the amino acid sequence of said preselected olfactory receptor protein to known amino acid sequences of transmembrane proteins having known, secondary and tertiary structures, said known amino acid sequence of said transmembrane proteins being selected from the group consisting of G-protein coupled receptors;

          (c) ~~S~~selecting at least one of said known amino acid sequences of transmembrane proteins by determining which of said known amino acid sequences has the highest degree of sequence homology with the amino acid sequence of said preselected olfactory receptor protein;

20           (d) ~~U~~using said selected sequence to approximate the secondary and tertiary structure of said preselected olfactory receptor protein;

          (e) ~~U~~using said approximated secondary and tertiary structures of said olfactory receptor protein to identify a likely binding domain of said olfactory receptor protein for said ligand;

(f) Ssynthesizing a polypeptide having the primary structure of said likely binding domain; and

(g) Aattaching said synthesized polypeptide to the surface of a transducer.

5        2. A method of making a biosensor capable of detecting a gas molecule, the method comprising:

obtaining an amino acid sequence of an olfactory receptor protein ORP;

using the amino acid sequence of the ORP to compute a predictive secondary structure of the ORP and predict transmembrane fragments of the ORP;

10        comparing the amino acid sequence of the ORP with G-protein coupled receptors (GPCRs) by Basic Local Alignment Search Tool (BLAST) to find a template protein having the highest primary sequence homology with the ORP, wherein the primary, secondary and tertiary structures of the GPCRs are known and the secondary structures of the GPCRs are similar to the predictive secondary structure  
15        of the ORP;

using the tertiary structure of the template protein to be an initial tertiary structure for the ORP to compute a predictive tertiary structure of the ORP by energy minimization and molecular dynamics to get three coordinates of each ORP's atom;

treating the ORP as a rigid body, according to the three coordinates of each  
20        ORP's atom, to calculate geometrical binding domains of the ORP with a gas molecule by geometric recognition algorithms;

relaxing the ORP's structure to further calculating the most probably binding domains, based on the geometrical binding domains, of the ORP with the gas molecule;

synthesizing peptides according to the primary amino acid sequence of the likely binding domains; and

attaching the synthesized peptide to a surface of a transducer having a gold electrode on a piezoelectric quartz to be a receptor of a biosensor.

5

3. The method of claim 2, wherein a molecule containing thiol functional group is added to a terminal of the synthesized peptides when two terminals of the synthesized peptides do not have thiol functional group.

10

4. The method of claim 3, wherein attaching the synthesized peptide to the surface of the transducer comprises:

dissolving the synthesized peptides in a solvent to form a peptide solution; and dipping the gold electrode in the peptide solution under room temperature.

15

5. A method of finding candidates for peptides being covered on an electronic nose for detecting a gas, the method comprising:

obtaining an amino acid sequence of an olfactory receptor protein ORP;

using the amino acid sequence of the ORP to compute a predictive secondary structure of the ORP and predict transmembrane fragments of the ORP;

20

comparing the amino acid sequence of the ORP with G-protein coupled receptors (GPCRs) by Basic Local Alignment Search Tool (BLAST) to find a template protein having the highest primary sequence homology with the ORP, wherein the primary, secondary and tertiary structures of the GPCRs are known and the secondary structures of the GPCRs are similar to the predictive secondary structure

of the ORP;

using the tertiary structure of the template protein to be an initial tertiary structure for the ORP to compute a predictive tertiary structure of the ORP by energy minimization and molecular dynamics to get three coordinates of each ORP's atom;

5 treating the ORP as a rigid body, according to the three coordinates of each ORP's atom, to calculate geometrical binding domains of the ORP with a gas molecule by geometric recognition algorithms; and

relaxing the ORP's structure to further calculating the most probably binding domains, based on the geometrical binding domains, of the ORP with the gas  
10 molecule, whereby amino acid sequences of the most probably binding domains are candidates for peptides being covered on an electronic nose.

## **ABSTRACT OF THE DISCLOSURE**

A method for rapidly designing a biosensor which binds a preselected ligand to a layer of polypeptides. The polypeptide layer is made of relatively short molecules  
5 representative of a binding domain of an Olfactory Receptor Protein. The method uses a series of predictive structure determinations to obtain the sequence of the polypeptides applied to a transducer surface.
